My Gilbert was diagnosed at the age of 10. He was starting to show other symptoms of slowing down and wasn't really as active as he used to be. We weren't really concerned until he started throwing up water and then eventually food. We finally got him checked out when he started puking after almost every meal. He had hypothyroidism and also megaesophagus. We started feeding in the bailey chair but it was really hard. He got aspiration pneumonia and died about 4 months after diagnosis.

We brought a puppy home at 8 weeks and then noticed he was always burping up his food. It kept getting worse and the vet suggested we do a barium study or something? They saw the heart looping around the esophagus. He ended up having PRAA and needed surgery to correct it. However, he's made almost a full recovery! He doesn't eat in a bailey chair and is normal besides spitting up water sometimes. He'll be 9 next month!

Our dog started limping about 2 years ago now? Right before his 4th birthday. He seemed to sort of drag his feet and then was also spitting up his food. Something had to be wrong so we got him checked out. He was diagnosed with MG. He is on some medication now and seems to be pretty stable. We feed him in the bailey chair. He still regurgitates often and some days are better than others. He's still trucking along though.

I had a dog that was diagnosed with congenital megaesophagus. She was a puppy and really struggled with keeping any of her food down. We started feeding her upright and that helped a lot! Over time it seemed like she needed to sit upright for less and less time. It got to the point of her not really needing a bailey chair but we kept it around for relapses. She'd have a rough time every few years where she'd throw up more. She ended up getting AP twice, and the last time she passed away. However, she lived a long life and made it to 13.
